

CS173: Intermediate Programming

Complex ADT

Overview	
The Complex data structure stores and manipulates complex numbers of the form $a + bi$ where a and b are real numbers. This Complex type supports a multitude of arithmetic operations pertinent to complex numbers; these operations are described below.	
Constructors	
default	A new Complex data type should default to the value of $0 + 0i$. <code>Complex c;</code>
copy	Create a new Complex type from an existing one. <code>Complex c1(c2);</code>
Complex(a,b)	We should be able to specify a new Complex type by giving its real and imaginary components. The imaginary part defaults to 0. <code>Complex c1(2, 3.1); Complex c2(2.5);</code>
Operators	
addition	Should support addition between two complex numbers, complex and int, and complex and float. <code>c1 = c2 + c3; c1 = c2 + 5.5;</code>
subtraction	Should support subtraction between two complex numbers, complex and int, and complex and float. <code>c1 = c2 - c3; c1 = c2 - 5;</code>
multiplication	Should support multiplication between two complex numbers, complex and int, and complex and float. <code>c1 = c2 * c3; c1 = c2 * 5.5;</code>
division	Should support division between two complex numbers, complex and int, and complex and float. <code>c1 = c2 / c3; c1 = c2 / 5;</code>
conjugate	The \sim operator returns the complex conjugate. <code>c1 = ~c2;</code>
negation	The $-$ operator returns the negative of a complex. <code>c1 = -c2;</code>
exponentiation	The \wedge operator should raise a complex number to an integer power. <code>c1 = c2^x;</code> (where x is integer only)
abs	The abs method should return the distance from the origin. <code>c1.abs()</code>

Modifiers and Accessors	
setReal	Sets the real part of the complex number. <code>c1.setReal(5);</code>
getReal	Gets the real part of the complex number. <code>float f = c1.getReal();</code>
setImag	Sets the imaginary part of the complex number. <code>c1.setImag(5);</code>
getImag	Gets the imaginary part of the complex number. <code>float f = c1.getImag();</code>
Other	
assignment operator	Allows assignment of values between complex numbers. <code>c1 = c2;</code>
destructor	Cleans up the complex class.
equality operator	Equal if both real and imaginary parts are equal. <code>c1 == c2;</code>
inequality operator	True if either real or imaginary parts are not equal. <code>c1 != c2;</code>
cout <<	Allows printing of a complex number as a string " $a + bi$ ". <code>cout << c1 << endl;</code> Consider special cases: print $a+0i$ as a print $a+1i$ as $a+i$ print $0+bi$ as bi print $a+-bi$ as $a-bi$
cin>>	Allows reading of a complex number as a string " $a+bi$ ". <code>cin >> c1;</code> reads: $a+bi$, $a-bi$, $-a+bi$, $-a-bi$, $a+-bi$, $+a+bi$ reads: a , $-a$, $+a$, bi , $-bi$, $+bi$ where a, b can be integers or reals with decimal points
